## 4.0 INTRODUCTION

Electrochemistry is the branch of physical chemistry which deals with the study of interconversion of chemical energy and electrical energy

### ELECTROCHEMICAL CELL
**Galvanic cell  or Voltaic cell          Electrolytic cell.**

• Chemical energy → Electrical energy     • Electrical energy → Chemical energy

• Spontaneous redox reaction              • Non spontaneous redox reaction

## 4.1 CONDUCTORS

Substances which allow electric current to flow through them are called conductors.

Examples - Metals, Aqueous solution of acids, bases and salts, fused salts and impure water etc.

**Conductors are of two types -**   (i)  Metallic conductors or electronic conductors

(ii) Electrolytic conductors or ionic conductors

**(i)  Metallic conductors** : The conductors which conduct electric current by the movement of electrons without undergoing any  chemical change are known as metallic conductors.

Metals - Cu, Ag, Fe, Al etc, non metals - graphite

**(ii) Electrolytic conductors** : Those substances which conduct the electric current through ions in aqueous solution or in molten state are called electrolytic conductors.

• **Strong electrolyte :** Electrolytes which are completely ionized in aqueous solution are called strong electrolytes.

**Ex. :** Salts, strong acids and strong bases.

• **Weak electrolyte :-** Electrolytes which are not completely ionized in aqueous solution are called weak electrolytes.

**Ex. :** $CH_3COOH$, HCN, $NH_3$, amine, etc.

### Difference between metallic and electrolytic conductor

| | Metallic conductor | Electrolytic conductor |
|---|---|---|
| (i) | Charge carriers are free electrons. | Charge carriers are free ions. |
| (ii) | Flow of electricity takes place without any chemical change. | Flow of electricity takes place by chemical changes at electrodes. |
| (iii) | No transfer of matter takes place. | Transfer of matter takes place in the form of ions. |
| (iv) | Resistance is due to vibration of Kernels. | Resistance is due to inter ionic attraction and viscosity of medium. |
| (v) | The resistance increases with the increase in temperature. | The resistance decreases with the increase in temperature. |
| (vi) | Faraday's laws of electrolysis are not followed. | Faraday's laws of electrolysis are followed. |

## 4.2 ELECTROLYTIC CONDUCTANCE

**(a)** **Resistance (R) :-** Metallic and electrolytic conductors obey ohm's law according to which the resistance of a conductor is the ratio of the applied potential difference (V) to the current (I) flowing .

$$R = \frac{V}{I}$$     R is expressed in ohms.

**(b)** **Conductance (G) :-** It is the property by virtue of which it favours flow of current. The conductance of a conductor is equal to reciprocal of resistance $G = \frac{1}{R}$

unit of G is **mho** or **ohm⁻¹** or **Siemens (S)**.

**(c)** **Specific resistance/Resistivity (ρ) :-** The resistance (R) of a conductor is directly proportional to its length (ℓ) and inversely proportional to its area of cross section (A).

$$R \propto \frac{\ell}{A} \quad ; \quad R = \rho\frac{\ell}{A}$$

$$R = \rho.\frac{\ell}{A} \quad ; \quad \rho = R.\frac{A}{\ell}$$

If $\ell$ = 1 cm, A = 1 cm², therefore $\rho = R$

$\because$ V = A × $\ell$ = 1 cm³

Therefore resistance offered by 1 cm³ electrolytic solution is known as resistivity.

Unit of ρ → ohm cm

**(d)** **Specific conductance/ Conductivity (κ) :-**

It is defined as the reciprocal of specific resistance, $\kappa = \frac{1}{\rho}$

$$R = \rho\frac{\ell}{A}$$

$$\frac{1}{\rho} = \frac{1}{R}.\frac{\ell}{A}$$

$$\kappa = G \times G^*$$

Specific conductance = Conductance × Cell constant

Hence specific conductivity of a solution is defined as the conductance offered by 1 cm³ of electrolytic solution.     Unit of κ is ohm⁻¹ cm⁻¹

**Cell constant :**

$$G^* = \frac{\ell}{A} \; ; \text{ Its unit is cm}^{-1}$$

**(e) Molar conductivity or Molar conductance :- ($\Lambda_m$, $\lambda_m$ or $\mu$) :** It is defined as the conductance of all the ions produced by one mole of electrolyte present in the given volume of solution.

$$\Lambda_m = \kappa \times V$$

V = Volume of solution containing 1 mol of electrolyte.

If concentration of solution is M - mol per litre then

$$\Lambda_m = \frac{\kappa \times 1000}{M} \quad \boxed{\text{Unit} \rightarrow \text{ohm}^{-1} \text{ cm}^2 \text{ mol}^{-1}}$$

**(f) Equivalent conductivity or Equivalent conductance ($\Lambda_{eq}$ or $\lambda_{eq}$) :-** It is defined as the conductance of all the ions produced by one gram equivalent of the electrolyte in the given volume of solution.

$$\Lambda_{eq} = \kappa \times V$$

V = Volume of solution containing 1 g-eq of electrolyte.

If concentration of solution is N - gram equivalent per litre then

$$\Lambda_{eq} = \frac{\kappa \times 1000}{N} \quad \boxed{\text{Unit} \rightarrow \text{ohm}^{-1} \text{ cm}^2 \text{ eq}^{-1}}$$

● **Relation between $\Lambda_{eq.}$ and $\Lambda_m$**

$$\Lambda_m = \frac{\kappa \times 1000}{M} \text{ and } \Lambda_{eq.} = \frac{\kappa \times 1000}{N}$$

We know that    Normality = Valency Factor × Molarity . So $\boxed{\Lambda_{eq} = \dfrac{\Lambda_m}{V.F.}}$

───────── **Illustrations** ─────────

**Illustration 1.** The resistance of a 1N solution of salt is 50 $\Omega$. Calculate the equivalent conductance of the solution, if the two platinum electrodes in solution are 2.1 cm apart and each having an area of 4.2 cm$^2$.

**Solution.** $\kappa = \dfrac{1}{\rho} = \dfrac{1}{R}\left(\dfrac{\ell}{A}\right) = \dfrac{1}{50} \times \dfrac{2.1}{4.2} = \dfrac{1}{100}$ and $\Lambda_{eq.} = \dfrac{\kappa \times 1000}{N} = \dfrac{1}{100} \times \dfrac{1000}{1} = 10$ ohm$^{-1}$ cm$^2$ eq$^{-1}$

**Illustration 2.** Which of the following have maximum molar conductivity.
(i) 0.08 M solution and its specific conductivity is $2 \times 10^{-2}$ $\Omega^{-1}$ cm$^{-1}$.
(ii) 0.1 M solution and its resistivity is 50 $\Omega$ cm.

**Solution.** (i) $\Lambda_m = \dfrac{\kappa \times 1000}{M} = 2 \times 10^{-2} \times \dfrac{1000}{0.08} = 250$ $\Omega^{-1}$ cm$^2$ mol$^{-1}$

(ii) $\Lambda_m = \dfrac{\kappa \times 1000}{M}$ , $\because \kappa = \dfrac{1}{\rho}$, $\therefore \Lambda_m = \dfrac{1}{50} \times \dfrac{1000}{0.1} = 200$ $\Omega^{-1}$ cm$^2$ mol$^{-1}$

So, the molar conductivity of 0.08 M solution will be greater than 0.1 M solution

**Illustration 3.** The conductance of a salt solution (AB) measured by two parallel electrodes of area 100 cm$^2$ separated by 10 cm was found to be 0.0001 $\Omega^{-1}$. If volume enclosed between two electrodes contain 0.5 mol of salt. What is the molar conductivity (Scm$^2$ mol$^{-1}$) of salt at same concentration.
(A) 0.01                         (B) 0.02
(C) $2 \times 10^{-5}$                  (D) none of these
**Solution** $G^* = \dfrac{\ell}{a} = \dfrac{10}{100} = 0.1$; G = 0.0001 S; V = 100 × 10 = 1000 cm$^3$ = 1 litre

$\kappa = G \, G^* = 0.1 \times 0.0001 = 10^{-5}$

$\Lambda_m = \dfrac{\kappa \times 1000}{M} = \dfrac{(0.1 \times 0.0001) \times 1000}{0.5} = 0.02$ S cm$^2$ mol$^{-1}$

## 4.3 FACTORS AFFECTING ELECTROLYTIC CONDUCTANCE

**(a) Inter ionic attraction :-** If inter ionic attraction between ions of solute is more, then the conductance will be less.

**(b) Polarity of solvent :-** If solvent has high-dielectric constant then the ionization and conductance will be higher.

**(c) Viscosity of medium :-** On increasing the viscosity of medium, the conductance decreases.

**(d) Temperature :-** As the temperature of electrolytic solution is increased, the conductance increases because K.E. of the ions increases and all types of attraction forces decrease and the viscosity of medium decreases.

**(e) Hydrated size :** Due to hydration of ions conductance decreases.

**(f) Dilution :-**

(i) On increasing the dilution conductance (G) increases.

For strong electrolyte on dilution interionic force of attraction decreases therefore conductance increases.

For weak electrolyte with dilution degree of dissociation ($\alpha$) increases therefore conductance increases.

(ii) On dilution specific conductance decreases because on dilution number of ions in 1 ml solution decreases.

(iii) On dilution equivalent and molar conductance increases because with dilution normality or molarity decreases

## DETERMINATION OF MOLAR CONDUCTANCE OF ELECTROLYTES AT INFINITE DILUTION

Debye Huckel Onsager equation –

$\Lambda_m = \Lambda_m^\infty - b\sqrt{C}$   [only for strong electrolyte]

where $\Lambda_m$ = molar conductance at concentration C,

$\Lambda_m^\infty$ = molar conductance at $\infty$ dilution,

b = constant and its value is same for a particular type of electrolyte.

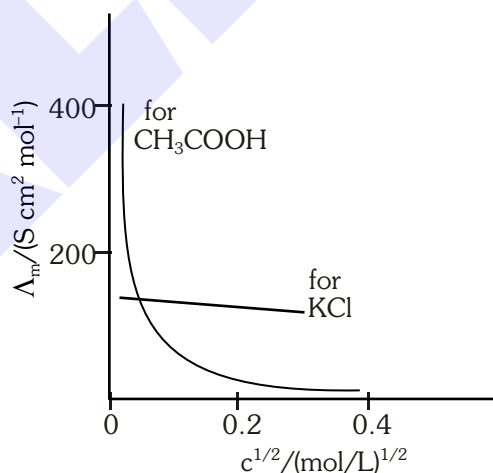

If a graph is plotted between $\Lambda_m$ vs $\sqrt{C}$ a straight line is obtained for strong electrolyte. On extrapolation this line touches $\Lambda_m$ axis. Therefore $\Lambda_m^\infty$ for strong electrolyte can be found out from intercept. For weak electrolyte the slope of curve is not constant so it can not be extrapolated to obtain $\Lambda_m^\infty$.

## 4.4 KOHLRAUSCH'S LAW OF INDEPENDENT MIGRATION OF IONS

At infinite dilution when dissociation of electrolyte is complete; each ion makes a definite contribution towards equivalent conductivity of any electrolyte irrespective of the nature of other ion associated with it.

This law states that the equivalent conductivity of any electrolyte at infinite dilution ($\Lambda_{eq.}^{\infty}$) is the sum of equivalent ionic conductivities of the cation and anion given by the electrolytes at infinite dilution.

$$\boxed{\Lambda_{eq}^{\infty} = \lambda_c^{\infty} + \lambda_a^{\infty}}$$

Where $\lambda_c^{\infty}$ = equivalent conductance of cation at infinite dilution.

$\lambda_a^{\infty}$ = equivalent conductance of anion at infinite dilution.

For $A_xB_y \rightarrow xA^{y+} + yB^{x-}$

In terms of molar conductances of cation and anion

$$\boxed{\Lambda_{eq}^{\infty} = \frac{1}{y}\lambda_{m(c)}^{\infty} + \frac{1}{x}\lambda_{m(a)}^{\infty}}$$

Where $\lambda_{m(c)}^{\infty}$ = Limiting molar conductance of cation .

$\lambda_{m(a)}^{\infty}$ = Limiting molar conductance of anion .

y = charge on cation

x = charge on anion

$$\boxed{\Lambda_m^{\infty} = x\lambda_{m(c)}^{\infty} + y\lambda_{m(a)}^{\infty}}$$

Where x = Stoichiometric coefficient of cation

y = Stoichiometric coefficient of anion

─────────────── **Illustrations** ───────────────

**Illustration 4.** Calculate $\Lambda_m^{\infty}$ of oxalic acid, given that

$$\Lambda_{eq}^{\infty} \, Na_2C_2O_4 = 400 \, \Omega^{-1} \, cm^2 \, eq^{-1}$$

$$\Lambda_m^{\infty} \, H_2SO_4 = 700 \, \Omega^{-1} \, cm^2 \, mol^{-1}$$

$$\Lambda_{eq}^{\infty} \, Na_2SO_4 = 450 \, \Omega^{-1} \, cm^2 \, eq^{-1}$$

**Solution** $\quad \Lambda_m^{\infty} \, H_2C_2O_4 = 700 + 800 - 900 = 600 \, \Omega^{-1} \, cm^2 \, mol^{-1}$

## 4.5 APPLICATIONS OF KOHLRAUSCH'S LAW :

**(a)** **To calculate conductance of weak electrolyte.**

**(b)** **To calculate degree of dissociation :**

Degree of dissociation $\alpha = \dfrac{\Lambda_{eq}}{\Lambda_{eq}^{\infty}} = \dfrac{\text{equivalent conductance at a given concentration}}{\text{equivalent conductance at infinite dilution}}$

or $\alpha = \dfrac{\Lambda_m}{\Lambda_m^{\infty}} = \dfrac{\text{molar conductance at a given concentration}}{\text{molar conductance at infinite dilution}}$

**(c)** **To calculate dissociation constant of weak electrolyte**

$$\boxed{K_a = \frac{C\alpha^2}{(1-\alpha)}}$$

If $\alpha \leq 5\%$ then $K_a = C\alpha^2$

**(d) To calculate Solubility (S) and $K_{SP}$ of any sparingly soluble salt.**

Sparingly soluble salt means salt with very less solubility

Saturated solution of sparingly soluble salt can be considered as infinitely dilute solution.

In a saturated solution of sparingly soluble salt. $\Lambda_m = \dfrac{\kappa \times 1000}{M}$
M = Solubility (S).

$\Lambda_m$ (saturated) = $\Lambda_m^\infty = \dfrac{\kappa \times 1000}{\text{Solubility}}$ ; $S = \dfrac{\kappa \times 1000}{\Lambda_m^\infty}$

────────── **Illustrations** ──────────

**Illustration 5.** Equal volumes of 0.015 M $CH_3COOH$ & 0.015 M NaOH are mixed together. What would be the molar conductivity of mixture if conductivity of $CH_3COONa$ is $6.3 \times 10^{-4}$ S cm$^{-1}$

(1) 8.4 S cm$^2$ mol$^{-1}$  (2) 84 S cm$^2$ mol$^{-1}$

(3) 4.2 S cm$^2$ mol$^{-1}$  (4) 42 S cm$^2$ mol$^{-1}$

**Solution** $CH_3COOH + NaOH \longrightarrow CH_3COONa + H_2O$

| 0.015V | 0.015V | 0 | 0 |
|---|---|---|---|
| 0 | 0 | 0.015V | 0.015V |

[Salt] = $\dfrac{0.015V}{2V}$ M ; $\Lambda_m = \dfrac{6.3 \times 10^{-4} \times 1000}{0.015/2}$ = 84 S cm$^2$ mol$^{-1}$

**Illustration 6.** The dissociation constant of n-butyric acid is $1.6 \times 10^{-5}$ and the molar conductivity at infinite dilution is $380 \times 10^{-4}$ S m$^2$mol$^{-1}$. The specific conductance of the 0.01 M acid solution is

(1) $1.52 \times 10^{-5}$ S m$^{-1}$  (2) $1.52 \times 10^{-2}$ S m$^{-1}$

(3) $1.52 \times 10^{-3}$ S m$^{-1}$  (4) None

**Solution** $K_a = \dfrac{c\alpha^2}{1-\alpha} \Rightarrow 1.6 \times 10^{-5} = \dfrac{0.01 \times \alpha^2}{1-\alpha}$

$\alpha = \sqrt{\dfrac{1.6 \times 10^{-5}}{0.01}} = \sqrt{1.6 \times 10^{-3}} = 0.04$ ; $\alpha = \dfrac{\Lambda_m}{\Lambda_m^\infty}$ ; $\Lambda_m = 0.04 \times 380 \times 10^{-4}$

$\Lambda_m = \dfrac{\kappa \times 10^{-3}}{M}$

$\kappa = \dfrac{0.04 \times 380 \times 10^{-4} \times 0.01}{10^{-3}} = 1.52 \times 10^{-2}$ S m$^{-1}$

**Illustration 7.** The conductivity of a saturated solution of $Ag_3PO_4$ is $9 \times 10^{-6}$ S m$^{-1}$ and its equivalent conductivity is $1.50 \times 10^{-4}$ S m$^2$ eq$^{-1}$. The $K_{sp}$ of $Ag_3PO_4$ is

(1) $4.32 \times 10^{-18}$  (2) $1.8 \times 10^{-9}$  (3) $8.64 \times 10^{-13}$  (4) None of these

**Solution** $\Lambda_{eq} = \kappa \times \dfrac{1000}{N}$ ; $1.50 \times 10^{-4} \times 10^4 = 9 \times 10^{-6} \times 10^{-2} \times \dfrac{1000}{N}$ ; $N = 6 \times 10^{-5}$

$S = M = \dfrac{N}{n_f} = \dfrac{6 \times 10^{-5}}{3} = 2 \times 10^{-5}$ mol L$^{-1}$

$Ag_3PO_{4(s)} \rightleftharpoons 3\,Ag^+ + PO_4^{3-}$

(a–S)  3 S  S

$K_{sp} = (3S)^3 \cdot S = 27 \cdot S^4$

$= 27 \times (2 \times 10^{-5})^4 = 4.32 \times 10^{-18}$

**BEGINNER'S BOX-1**

**1.** The resistance of 1 N solution of $CH_3COOH$ is 250 Ω, when measured in a cell of cell constant 1.15 $cm^{-1}$. The equivalent conductance will be

(1) 4.6 $Ω^{-1}$ $cm^2$ $eq^{-1}$                 (2) 9.2 $Ω^{-1}$ $cm^2$ $eq^{-1}$

(3) 18.4 $Ω^{-1}cm^2eq^{-1}$               (4) 0.023 $Ω^{-1}cm^2eq^{-1}$

**2.** The specific conductivity of N/10 KCl solution at 20°C is 0.012 $Ω^{-1}$ $cm^{-1}$ and the resistance of the cell containing this solution at 20°C is 56 Ω. The cell constant is

(1) 4.616 $cm^{-1}$       (2) 0.672 $cm^{-1}$       (3) 2.173 $cm^{-1}$       (4) 3.324 $cm^{-1}$

**3.** Molar conductances of $BaCl_2$, $H_2SO_4$ and HCl at infinite dilutions are $x_1$, $x_2$ and $x_3$, respectively. Equivalent conductance of $BaSO_4$ at infinite dilution will be :

(1) $\dfrac{[x_1 + x_2 - x_3]}{2}$      (2) $\dfrac{[x_1 - x_2 - x_3]}{2}$      (3) $2(x_1 + x_2 - 2x_3)$      (4) $\dfrac{[x_1 + x_2 - 2x_3]}{2}$

**4.** The ionization constant of a weak electrolyte is $25 \times 10^{-6}$ while the equivalent conductance of its 0.01 M solution is 19.6 S $cm^2$ $eq^{-1}$. The equivalent conductance of the electrolyte at infinite dilution (in S $cm^2$ $eq^{-1}$) will be

(1) 39.2            (2) 78.4            (3) 392            (4) 196

**5.** Which has maxmium conductivity :

(1) $[Cr(NH_3)_3 Cl_3]$      (2) $[Cr(NH_3)_4 Cl_2]Cl$      (3) $[Cr(NH_3)_5Cl]Cl_2$      (4) $[Cr(NH_3)_6]Cl_3$
## 4.6 ELECTRODE POTENTIAL :

- The potential developed between metal electrode and its ions in solution is known as electrode potential.

- The potential developed between metal electrodes and the solution of its ions at 1 M concentration at 1 bar pressure and 298 K is known as **standard electrode potential.**

- There are two types of electrode potential :-

**(a) Oxidation Potential (O.P.)**

- The electrode potential for oxidation half reaction

     $M(s) \rightarrow M^{+n}(aq) + ne^-$ ;      $E_{M/M^{n+}}$ = O.P.

- Tendency to get oxidised.

- **Greater the O.P. greater will be the tendency to get oxidised.**

**(b)** **Reduction Potential (R.P.)**

- The electrode potential for reduction half reaction

    $M^{+n}(aq) + ne^- \rightarrow M(s)$  ;        $E_{M^{n+}/M}$ = R.P.

- Tendency to get reduced.

- **Greater the R.P., greater will be the tendency to get reduced.**

- Electrode potential depends upon :
    - ○ Concentration of the solution.
    - ○ Nature of the metal.
    - ○ Pressure temperature conditions.

## 4.7 REFERENCE ELECTRODE :

- The potential of a single electode cannot be determined but the potential difference between two electrodes can be accurately measured using a reference electrode.

- An electrode is chosen as a reference with respect to which all other electrodes are valued.

### STANDARD HYDROGEN ELECTRODE (SHE) :

Representation : Pt, $H_2(g)$ | $H^+(1M)$

When acts as anode

   $H_2(g) \rightleftharpoons 2H^+ + 2e^-$

   $E^0_{H_2(g)/H^+(aq.)}$ = SOP

When acts as cathode

   $2H^+ + 2e^- \rightleftharpoons H_2(g)$
   $E^0_{H^+/H_2(g)}$ = SRP

- For SHE electrode potential is arbitrarily assumed to be zero at all temperature.

    SOP = –SRP = 0 for SHE.

- To calculate standard potential of any other electrode a cell is coupled with standard hydrogen electrode (SHE) and it's potential is measured that gives the value of electrode potential of that electrode.

**4.8 CELL POTENTIAL ($E^\circ_{cell}$) :**

$E^\circ_{cell}$ = SRP of cathode – SRP of anode

$E^\circ_{cell}$ = SRP of cathode + SOP of anode

$E^\circ_{cell}$ = SOP of anode – SOP of cathode

**4.9 ELECTROCHEMICAL SERIES**

Arrangement of different elements on the basis of their SRP values is known as electrochemical series or activity series.

| Electrode | Reaction | SRP (at 298 K) |
|---|---|---|
| Li | $Li^+ + e^- \rightarrow Li(s)$ | – 3.05 V |
| K | $K^+ + e^- \rightarrow K\ (s)$ | – 2.93 V |
| Ba | $Ba^{+2} + 2e^- \rightarrow Ba$ | – 2.91 V |
| Ca | $Ca^{+2} + 2e^- \rightarrow Ca(s)$ | – 2.87 V |
| Na | $Na^+ + e^- \rightarrow Na(s)$ | – 2.71 V |
| Mg | $Mg^{+2} + 2e^- \rightarrow Mg(s)$ | – 2.36 V |
| Al | $Al^{3+} + 3e^- \rightarrow Al$ | – 1.66 V |
| Mn | $Mn^{+2} + 2e^- \rightarrow Mn$ | – 1.18 V |
| $H_2O$ | $H_2O(l) + e^- \rightarrow \frac{1}{2}H_2 + OH^-$ | – 0.828 V |
| Zn | $Zn^{+2} + 2e^- \rightarrow Zn(s)$ | – 0.76 V |
| Cr | $Cr^{+3} + 3e^- \rightarrow Cr(s)$ | – 0.74 V |
| Fe | $Fe^{2+} + 2e^- \rightarrow Fe$ | – 0.44 V |
| Cd | $Cd^{+2} + 2e^- \rightarrow Cd(s)$ | – 0.40 V |
| Co | $Co^{2+} + 2e^- \rightarrow Co$ | – 0.28 V |
| Ni | $Ni^{+2} + 2e^- \rightarrow Ni(s)$ | – 0.25 V |
| Sn | $Sn^{+2} + 2e^- \rightarrow Sn(s)$ | – 0.14 V |
| Pb | $Pb^{+2} + 2e^- \rightarrow Pb(s)$ | – 0.13 V |
| $H_2$ | $2H^+ + 2e^- \rightarrow H_2(g)$ | 0.00 V |
| Cu | $Cu^{2+} + 2e^- \rightarrow Cu(s)$ | 0.34 V |
| $I_2$ | $I_2 + 2e^- \rightarrow 2I^-$ | 0.54 V |
| Fe | $Fe^{3+} + e^- \rightarrow Fe^{2+}$ | 0.77 V |
| Hg | $Hg_2^{2+} + 2e^- \rightarrow Hg(l)$ | 0.79 V |
| Ag | $Ag^+ + e^- \rightarrow Ag$ | 0.80 V |
| Hg | $Hg^{2+} + 2e^- \rightarrow Hg(l)$ | 0.85 V |
| $Br_2$ | $Br_2 + 2e^- \rightarrow 2Br^-$ | 1.09 V |
| Pt | $Pt^{+2} + 2e^- \rightarrow Pt$ | 1.20 V |
| $O_2$ | $\frac{1}{2}O_2 + 2H^+ + 2e^- \rightarrow H_2O(\ell)$ | 1.23 V |
| $Cl_2$ | $Cl_2 + 2e^- \rightarrow 2\ Cl^-$ | 1.36 V |
| Au | $Au^{+3} + 3e^- \rightarrow Au(s)$ | 1.40 V |
| $F_2$ | $F_2 + 2e^- \rightarrow 2F^-$ | 2.87 V |

Increasing strength of reducing agent

Increasing strength of oxidising agent

## 4.10 APPLICATIONS OF ELECTROCHEMICAL SERIES

**(i)** **Oxidising and reducing power –**

Oxidising power $\propto$ SRP $\propto \dfrac{1}{\text{SOP}}$

Reducing power $\propto$ SOP $\propto \dfrac{1}{\text{SRP}}$

**(ii)** **Reactivity of metals –**

Reactivity of metal $\propto$ SOP $\propto \dfrac{1}{\text{SRP}}$

• Li is most reactive metal.

**(iii)** **Reactivity of non-metals –**

Reactivity of non-metal $\propto$ SRP $\propto \dfrac{1}{\text{SOP}}$

• $F_2$ is most reactive non-metal.

**(iv)** **Displacement reactions in solution –**

More reactive metal / non-metal displaces less reactive metal / non-metal in their solution.

• $Cu + 2\,AgNO_3 \rightarrow Cu(NO_3)_2 + 2\,Ag$

$Ag + Cu(NO_3)_2 \rightarrow$ No reaction

• $2\,KI + Cl_2 \rightarrow 2\,KCl + I_2$

$I_2 + 2\,KCl \rightarrow$ No reaction

## 4.11 GALVANIC CELL :

● It has two **half–cells**, each having a beaker containing a metal strip that dips in its aqueous salt solution.

● The metal strips are called **electrodes** and are connected by a conducting wire.

● Two solutions are connected by a **salt bridge.**

● The oxidation and reduction half reactions occur at separate electrodes and electric current flows through the wire.

$Zn(s) \rightarrow Zn^{+2}(aq) + 2e^- \quad Cu^{+2}(aq) + 2e^- \rightarrow Cu(s)$
### Salt Bridge and its functions :

Salt bridge is inverted U-tube containing solution of inert electrolyte with agar-agar or gelatin to convert into semi solid form.

Ions of inert electrolyte do not involve in any chemical change.

The electrolyte in salt bridge should be such that speed of it's cation is nearly equal to speed of it's anion.

Ex. $KCl$, $KNO_3$, $NH_4NO_3$

If $Ag^+$ , $Hg_2^{+2}$, $Pb^{+2}$, $Tl^+$ ions are present in a cell then KCl is not used because there can be formation of precipitate of $AgCl$, $Hg_2Cl_2$, $PbCl_2$ or $TlCl$.

### Functions

- It connects the solution of two half cell to complete the circuit.
- It maintains the electrical neutrality of the solution in order to give continuous flow or generation of current.
- If the salt bridge is removed then voltage drops to zero.
- It prevents the liquid -liquid junction potential. The potential difference which arises between two solutions when they brought in contact with each other.

## Cell Representation :

We require two half cells to produce an electrochemical cell, which can be represented by following few rules;

- The anode half-cell is always written on the left followed on the right by cathode half cell.
- The separation of two phases (state of matter) is shown by a vertical line.
- The various materials present in the same phase are shown together using commas.
- The salt bridge is represented by a double slash $(\|)$.
- The significant features of the substance like pressure of a gas, concentration of ions etc. are indicated in brackets immediately after writing the substance.

  $Zn(s) \mid ZnSO_4 \ (aq) \parallel CuSO_4(aq) \mid Cu(s)$
## 4.12 NERNST EQUATION :

It gives relation between electrode potential/ EMF of cell and concentration of electrolytic solution.

Walther Nernst derived a relation between free energy change (ΔG) and Reaction quotient (Q).

$$\Delta G = \Delta G° + RT \ln Q \qquad \qquad ..(1)$$

where ΔG and ΔG° are free energy change and standard free energy change; 'Q' is reaction quotient.

$$-\Delta G = nFE \qquad and -\Delta G° = nFE°$$

Thus from Eq. (1), $-nFE = -nFE° + RT \ln Q$

$$E = E^0 - \frac{2.303 \, RT}{nF} \log Q$$

Where - $E^0$ = standard electrode potential,

$R$ = gas constant,

$T$ = temperature (in K)
$F$ = Faraday (96500 coulomb $mol^{-1}$),

$n$ = number of moles of $e^-$ gained lost or transferred in balanced equation.

At 25°C, above equation may be written as $\boxed{E = E^0 - \frac{0.0591}{n} \log Q}$

$$\boxed{E = E^0 - \frac{0.0591}{n} \log \frac{[P]}{[R]}}$$

In general, for a redox cell reaction involving the transference of n electrons

$$aA + bB \longrightarrow cC + dD$$

$$E_{Cell} = E°_{Cell} - \frac{0.0591}{n}\log\frac{[C]^c[D]^d}{[A]^a[B]^b} \text{ or } \quad E_{cell} = E°_{cell} - \frac{0.0591}{n}\log\frac{[Product]}{[Reactant]}$$

## 4.13 APPLICATIONS OF NERNST EQUATION

### (i) Calculation of electrode potential ($E_{RP}$ or $E_{OP}$) –

$$M^{+n} + ne^- \xrightarrow{\text{Reduction}} M(s)$$

$$E_{RP} = E_{RP}^0 - \frac{0.0591}{n}\log\frac{[M]}{[M^{+n}]}$$

$$\boxed{E_{RP} = E_{RP}^0 - \frac{0.0591}{n}\log\frac{1}{[M^{+n}]}}$$

If $[M^{+n}]$ increases, then $E_{RP}$ increases

### (ii) Calculation of electrode potential and pH of hydrogen electrode –

$$2H^+ + 2e^- \to H_2(g)$$

$$E_{RP} = E_{RP}^0 - \frac{0.0591}{2}\log\frac{P_{H_2}}{[H^+]^2}$$

$$\because \quad E_{RP}^0 = 0 ; \quad E_{RP} = 0 - \frac{0.0591}{2}\log\frac{1}{[H^+]^2} \qquad [P_{H_2} \text{ is taken 1 atm }]$$

$$E_{RP} = 0.0591 \log[H^+]$$

$$\boxed{E_{RP} = -0.0591\,pH} \quad \boxed{E_{OP} = +0.0591\,pH}$$

,

### (iii) Calculation of EMF of cell ($E_{cell}$) –

$$eg. \qquad Zn(s) + Cu^{+2}(aq) \xrightarrow{n=2} Zn^{+2}(aq) + Cu(s)$$
$$\boxed{E_{cell} = E_{cell}^0 - \frac{0.0591}{2}\log\frac{[Zn^{+2}]}{[Cu^{+2}]}}$$

If $[Cu^{+2}]$ increases, then $E_{cell}$ increases

If $[Zn^{+2}]$ increases, then $E_{cell}$ decreases

### (iv) Prediction and feasibility of a cell reaction –

For a feasible cell reaction

$$\Delta G = -ve \qquad (\Delta G = -nFE_{cell})$$

$$E_{cell} = +ve$$

### (v) Calculation of equilibrium constant ($K_{eq}$) and $\Delta G°$ –

From Nernst equation –

$$E_{cell} = E_{cell}^0 - \frac{0.0591}{n}\log\frac{[P]}{[R]}$$

At equilibrium, $E_{cell} = 0$   and    $\dfrac{[P]}{[R]} = K_{eq}$

$$\boxed{E^0_{cell} = \dfrac{0.0591}{n} \log K_{eq}}$$

$E^0_{cell} = \dfrac{2.303RT}{nF} \log K_{eq}$

$n\, F\, E^0_{cell} = 2.303\, RT \log K_{eq}$

$$\boxed{\Delta G° = -2.303\, RT \log K_{eq}}$$

────────────── **Illustrations** ──────────────

**Illustration 8.**  Write cell representation for the following redox reaction,

$$Sn^{2+}\ (aq)\ +\ 2Ag^+\ (aq) \rightarrow Sn^{4+}(aq) + 2Ag(s).$$

**Solution**  The cell consists of a platinum wire anode dipped in $Sn^{+2}$ solution and a silver cathode dipped in $Ag^+$ solution therefore $Pt(s)\,|\ Sn^{2+}(aq),\ Sn^{4+}\ (aq)\ ||\ Ag^+\ (aq)\ |\ Ag(s)$.

**Illustration 9.**  Calculate the EMF of a Daniel cell when the concentration of $ZnSO_4$ and $CuSO_4$ are 0.001 M and 0.1 M respectively. The standard EMF of the cell is 1.1 V.

**Solution**  $Zn(s) + CuSO_4 \rightarrow ZnSO_4 + Cu$

$E_{cell} = E^0_{Cell} - \dfrac{0.0591}{2} \log \dfrac{\left[Zn^{2+}\right]}{\left[Cu^{2+}\right]} = 1.1 - \dfrac{0.0591}{2} \log \dfrac{10^{-3}}{10^{-1}} = 1.159$ V

**Illustration 10.**  Calculate $E^0$ and $E$ for the cell $Sn\,|\,Sn^{2+}$ (1M) $||\ Pb^{2+}(10^{-3}M)\ |\ Pb$, $E^0$ ($Sn^{2+}\,|\,Sn$) = –0.14V, $E^0$ ($Pb^{2+}\,|\,Pb$) = –0.13 V.  Is cell representation correct?

**Solution**  $E^0_{cell} = E^0_{Pb^{+2}/Pb} - E^0_{Sn^{+2}/Sn} = -0.13 - (-0.14) = + 0.01$ V

$E_{cell} = E^0_{cell} - \dfrac{0.0591}{2} \log \dfrac{[Sn^{+2}]}{[Pb^{+2}]} = +0.01 - \dfrac{0.0591}{2} \log\left[\dfrac{1}{10^{-3}}\right] = -0.078$ V cell with not work

**Illustration 11.**  Calculate the equilibrium constant for the reaction $Fe^{2+} + Ce^{4+} \rightleftharpoons Fe^{3+}\ +\ Ce^{3+}$,

[**Given :** $E^0_{Ce^{4+}/Ce^{3+}} = 1.44$ V; $E^0_{Fe^{3+}/Fe^{2+}} = 0.68$ V ]

Take $\dfrac{2.303\ RT}{F} = 0.06$ at 25 °C, log 4.68 = 0.67

**Solution**  $Fe^{2+} + Ce^{4+} \rightleftharpoons Fe^{3+} + Ce^{3+}$

$E° = 1.44 - 0.68 = 0.76V = \dfrac{.06}{1} \log K_C$ ;  $K_C = 4.64 \times 10^{12}$

**Illustration 12.**  The 0.1 M copper sulphate solution in which copper electrode is dipped at $25^0$C. Calculate the electrode potential of copper electrode [Given $E^0_{Cu^{+2}/Cu} = 0.34V$]

**Solution.**  $Cu^{+2} + 2e^- \rightarrow Cu(s)$

$E_{red} = E^0_{red} - \dfrac{0.059}{n} \log \dfrac{[Product]}{[Reactant]}$

Here n = 2 so $E = 0.34 - \dfrac{0.059}{2} \log 10$

$E = 0.34 - 0.03 = 0.31$ V

**Illustration 13.** Calculate the EMF of the cell $\quad Cr \mid Cr^{+3} (0.1M) \parallel Fe^{+2} (0.01M) \mid Fe$

(Given $E^{\circ}_{Cr^{+3}/Cr} = -0.75V$, $E^{\circ}_{Fe^{+2}/Fe} = -0.45$ V)

**Solution.** Half cell reactions are –

At Anode $\qquad [Cr \rightarrow Cr^{+3} + 3e^-] \times 2$

At Cathode $\qquad [Fe^{+2} + 2e^- \rightarrow Fe] \times 3$
_____

Cell reaction $\qquad 2Cr + 3Fe^{+2} \rightarrow 2Cr^{+3} + 3Fe$

$E^{\circ}_{cell}$ = Oxidation potential + Reduction potential = 0.75 + (–0.45) = 0.30 V

$$E_{cell} = E^0 - \dfrac{0.059}{n}\log\dfrac{[Product]}{[Reactant]} = 0.30 - \dfrac{0.059}{6}\log\dfrac{\left[Cr^{+3}\right]^2}{\left[Fe^{+2}\right]^3} = 0.30 - \dfrac{0.059}{6}\log\dfrac{\left[0.1\right]^2}{\left[0.01\right]^3}$$

$$= 0.30 - \dfrac{0.24}{6} = 0.26 \text{ V}$$

**Illustration 14.** For the cell $Pt(s) \mid H_2 (0.4 \text{ atm}) \mid H^+(pH=1) \parallel H^+ (pH = 2) \mid H_2 (0.1 \text{ atm}) \mid Pt$

The measured potential at 25°C is

(1) –0.1 V $\qquad$ (2) –0.5 V $\qquad$ (3) –0.041 V $\qquad$ (4) –0.030 V

**Solution** Anode reaction : $H_2(0.4 \text{ atm}) \rightarrow 2H^+ (10^{-1} \text{ M}) + 2e^-$

Cathode reaction : $2H^+ (10^{-2} \text{ M}) + 2e^- \rightarrow H_2 (0.1 \text{ atm})$
_____

Cell reaction $\qquad H_2(0.4 \text{ atm}) + 2H^+ (10^{-2} \text{ M}) \rightarrow 2H^+ (10^{-1} \text{ M}) + H_2 (0.1 \text{ atm})$
$$E = 0 - \dfrac{0.059}{2}\log\dfrac{(10^{-1})^2(0.1)}{(0.4)(10^{-4})} = -0.041V$$

**Illustration 15.** If $E^{\circ}_{Au^+/Au}$ is 1.69 V & $E^{\circ}_{Au^{3+}/Au}$ is 1.40 V, then $E^{\circ}_{Au^{3+}/Au^+}$ will be

(1) 0.19 V $\qquad$ (2) 2.945 V $\qquad$ (3) 1.255 V $\qquad$ (4) none

**Solution** $Au^+ + e^- \longrightarrow Au(s) \qquad E^{\circ} = 1.69$ V $\qquad ...(1) ; \Delta G^{\circ}_1$

$Au^{3+} + 3e^- \longrightarrow Au(s) \qquad E^{\circ} = 1.40$ V $\qquad ...(2) ; \Delta G^{\circ}_2$

From (2) – (1)

$Au^{3+} + 2e^- \longrightarrow Au^+ \; ...(3) ; \Delta G^{\circ}_3$
$\Delta G^{\circ}_3 = \Delta G^{\circ}_2 - \Delta G^{\circ}_1$

$-2 \times F \times E^{\circ} = -3 \times F \times 1.40 + 1 \times 1.69 \times F$

$E^{\circ} = 1.255$ V

## GOLDEN KEY POINTS

● The value of electrode potential does not depend on stoichiometry of half reactions as it is an intensive property.

● Gibb's free energy is extensive property.

● In electrolytic cell, cathode is negative terminal whereas in Galvanic cell cathode is positive terminal.

● Cell reaction is spontaneous, if
$$\Delta G = -ve \quad \text{or} \quad E_{cell} = +ve$$

● Cell reaction will be in equilibrium, if

e.g. $\quad \Delta G = 0 \quad$ or $\quad -nFE_{cell} = 0 \quad$ or $\quad E_{cell} = 0$

● **Work done by a cell :**

(i) Let 'n' faraday charge be taken out of a cell of EMF ' E ' ; then work done by the cell will be calculated as:

$$\text{Work} = \text{Charge} \times \text{Potential} = nF \times E$$

(ii) Work done by cell = Decrease in free energy

so $-\Delta G = nFE$ or $W_{max} = + nFE°$, where E° is standard EMF of the cell.

---

## BEGINNER'S BOX-2

**1.** Calculate $E°_{cell}$ for the following cell

$$Zn(s) \,|\, Zn^{+2}_{(aq.)} \,||\, Ag^+_{(aq)} \,|\, Ag(s) \quad E°_{Zn^{+2}/Zn} = -0.76V \;;\; E°_{Ag^+/Ag} = 0.80V$$

(1) 0.04 V            (2) – 1.56 V            (3) 1.56 V            (4) 0.84 V

**2.** Standard EMF of a galvanic cell involving $2e^-$ transfer is found to be 0.591 V at 25℃. Calculate equilibrium constant for the cell reaction

(1) $20^{10}$            (2) $10^{20}$            (3) $10^{200}$            (4) $200^{10}$

**3.** Calculate cell potential at 298 K for the following galvanic cell

$$Cd(s) \,|\, Cd^{+2}(aq.)(0.1M) \,||\, H^+_{(aq)}(0.1M) \,|\, H_2(g, 0.5\, atm) \,|\, Pt$$

$$E°_{Cd^{+2}/Cd} = -0.40V$$

(1) 0.38            (2) – 0.38            (3) 0.36            (4) – 0.36

**4.** Calculate $E°_{cell}$ of the following galvanic cell at 298 K ;

$$Ca(s) \,|\, Ca^{+2}_{(aq.)} \,||\, Fe^{+2}_{(aq)} \,|\, Fe(s)$$

$$E°_{Ca^{+2}/Ca} = -2.87V \;;\; E°_{Fe/Fe^{+2}} = 0.41V$$

(1) 2.46 V            (2) – 2.46 V            (3) 3.28 V            (4) – 3.28 V

**5.** Given $E°_{Ag^+/Ag} = 0.80$ V, $E°_{Mg^{2+}/Mg} = -2.37$ V, $E°_{Cu^{2+}/Cu} = 0.34$ V, $E°_{Hg^{2+}/Hg} = 0.79$ V.

Which of the following statement is correct

(1) $AgNO_3$ can be stored in copper vessel

(2) $Mg(NO_3)_2$ can not be stored in copper vessel

(3) $CuCl_2$ can be stored in silver vessel

(4) $HgCl_2$ can be stored in copper vessel

## 4.14 SOME SPECIAL CELLS

### (A) CONCENTRATION CELLS

A concentration cell is a form of galvanic cell that has two equivalent half cells of the same material having difference only in concentrations. For such cells anode and cathode are same so **$E°_{cell} = 0$**.

**eg.** Pt, $H_2(g)$ ($P_1$ atm) $|\, H^+$ ($C_1$) $||\, H^+(C_2) \,|\, H_2(g)$ ($P_2$ atm), Pt

**Anode Reaction :** $\quad H_2(P_1) \longrightarrow 2H^+(C_1) + 2e^-$

**Cathode Reaction :** $2H^+(C_2) + 2e^- \longrightarrow H_2(P_2)$

**Cell Reaction :** $\quad H_2(P_1) + 2H^+(C_2) \longrightarrow 2H^+(C_1) + H_2(P_2)$

$$E_{cell} = E°_{cell} - \frac{0.0591}{n} \log \frac{[P]}{[R]}$$

So, $E_{cell} = 0 - \frac{0.0591}{2} \log \left[ \frac{C_1}{C_2} \right]^2 \frac{P_2}{P_1}$

**Case 1 :** If $P_1 = P_2 = 1$ atm ; $E_{cell} = -\frac{0.059}{2} \log \left[ \frac{C_1}{C_2} \right]^2$

$$\boxed{E_{cell} = -0.0591 \log \left[ \frac{C_1}{C_2} \right]}$$

If $C_2 > C_1$ then $E_{cell} > 0$ and cell will be spontaneous.

**Case 2 :** If $C_1 = C_2$ $\quad E_{cell} = -\frac{0.0591}{2} \log \left[ \frac{P_2}{P_1} \right]$

$P_1 \neq P_2$

If $P_1 > P_2$ then $E_{cell} > 0$ and cell will be spontaneous.

**(B) REVERSIBLE CELLS :**

Those cell's in which chemical reactions are reversed by applying external emf in opposite directions known as reversible cells. A daniel cell is said to be reversible if it follows two conditions :

(i) When $E_{ext} > 1.1$ V (emf of daniel cell) : cell reactions reversed

(ii) When $E_{ext} = 1.1$ V (emf of daniel cell) ; equilibrium will be established.

• In general secondary cells are reversible in nature.

When $E_{ext} = 1.1$ V
(i) No flow of electron or current
(ii) No chemical reaction

When $E_{ext} > 1.1$ V
(i) Electron flow from Cu to Zn and current flow from Zn to Cu.
(ii) Zinc is deposited at the zinc electrode and copper dissolves at copper electrode.

## 4.15 ELECTROLYSIS

The process of chemical decomposition of an electrolyte by the passage of electricity is called electrolysis or electrolytic dissociation. It is carried out in **electrolytic cell** where electrical energy is converted into chemical energy. For electrolysis two suitable electrodes are immersed in the solution of an electrolyte. When an electric potential is applied between the electrodes, the positive ions move towards the cathode and negative ions move towards the anode. The gain of electrons (decrease in oxidation number) means reduction takes place at the cathode and loss of electrons (increase in oxidation number) means oxidation takes place at anode.

Electrolytic cell
There are two aspects of electrolysis :

**(A)    Qualitative aspects of electrolysis :-**

In qualitative aspect products formed at electrode are identified. At electode product formation depends up on the following :

(i)     Nature of electrolyte

(ii)    Nature of electrodes : The metal strip at which current enters is called **anode**; anode is positively charged in electrolytic cell. On the other hand, the electrode at which current leaves is called **cathode**. Cathode is negatively charged. There are two types of electrodes

(a)    Attackable : The attackable electrodes participate in the electrode reaction. They are made up of reactive metals like Zn, Cu, Ag etc in their respective solutions. In such electrodes, atom of the metal gets oxidised into the corresponding cation, which is passed into the solution. Thus, such anode gets dissolved and their mass decreases.

● If electrode is active at cathode, metal goes on depositing and at anode metal is dissolved. The process is called electroplating.

(b)    Non - attackable : Non-attackable electrodes do not participate in the electrode reaction as they are made up of unreactive elements like Pt, graphite etc. Such electrodes do not dissolve and their mass remain same.

● Among the two cations, that cation is discharged at the cathode which has higher reduction potential. Among the two anions, that anion will be discharged at the anode which has lower reduction potential or higher oxidation potential.

● The discharge of $NO_3^-, PO_4^{3-}$ and $SO_4^{2-}$ ions at anode does not commonly take place from aqueous solution.

(iii)   Concentration of electrolytic solution.

**Examples of electrolysis :**

**(a)    Electrolysis of Molten Sodium Chloride**

$$NaCl_{(molten)} \longrightarrow Na^+ + Cl^-$$

Reaction at anode (oxidation) :    $2Cl^- \longrightarrow Cl_2(g) + 2e^-$

Reaction at cathode (reduction) : $2Na^+ + 2e^- \longrightarrow 2Na(s)$

**(b)    Electrolysis of Sodium Chloride Solution**

On electrolysis of aqueous solution of NaCl, the possible species involved in half-reactions are $Na^+$, $Cl^-$ and $H_2O$.

The possible cathode half-reactions are

$Na^+(aq) + e^- \longrightarrow Na(s)$                        $E° = -2.71V$

$2H_2O(l) + 2e^- \longrightarrow H_2(g) + 2OH^-(aq)$     $E° = -0.83V$
Under the standard conditions, $H_2O$ is to be reduced in preference to $Na^+$ and Hydrogen is evolved at the cathode.

The possible anode half-reactions are
$$2Cl^-(aq) \longrightarrow Cl_2(g) + 2e^- \qquad E° = -1.36V$$

$$2H_2O(l) \longrightarrow O_2(g) + 4H^+(aq) + 4e^- \qquad E° = -1.23V$$
Under the standard-state conditions, $H_2O$ is to be oxidized in preference to $Cl^-$. But since electrode potentials, depend on concentrations it turns out that when the solution is concentrated enough in $Cl^-$, $Cl_2$ is the product; but in dilute solution, $O_2$ is the product.
**Starting with very dilute NaCl solutions, the oxidation potential of Cl⁻ is very negative, so H₂O is oxidised in preference to Cl⁻. But as the NaCl concentration increase, the oxidation potential of Cl⁻ increases until eventually Cl⁻ is oxidized in preference to H₂O. The product changes from O₂ to Cl₂.**

The half-reactions and cell reaction for the electrolysis of aqueous sodium chloride to chlorine and hydroxide ion are as follows:

$$2H_2O(l) + 2e^- \longrightarrow H_2(g) + 2OH^-(aq) \quad \text{(cathode)}$$

$$2\,Cl^-(aq) \longrightarrow Cl_2(g) + 2e^- \qquad \text{(anode)}$$

_____

$$2H_2O(l) + 2Cl^-(aq) \longrightarrow H_2(g) + Cl_2(g) + 2OH^-(aq)$$

Because the electrolysis started with sodium chloride, the cation in the electrolyte solution is $Na^+$. On evaporation of the electrolyte solution, sodium hydroxide NaOH is obtained.
**(c) Electrolysis of Molten lead bromide using inert (Pt/graphite) electrodes.**

**Cathode (reduction) :** $\qquad Pb^{2+} + 2e^- \rightarrow Pb(s) \qquad E^0 = -0.13$ V

**Anode (oxidation) :** $2Br^- \rightarrow Br_2(g) + 2e^- \qquad E^0 = -1.09$ V

Overall reaction $\qquad Pb^{+2} + 2Br^- \rightarrow Pb(s) + Br_2(g)$

$\qquad\qquad\qquad E_{cell} = -0.13 - 1.09 = -1.22$ V

$\qquad\qquad\qquad E_{ext} > 1.22$ V

**(d) Electrolysis of aq CuSO₄ using inert (Pt/graphite) electrode**

**Cathode (reduction) :** $\qquad Cu^{2+} + 2e^- \rightarrow Cu(s) \qquad\qquad\qquad E^0 = 0.34$ V

$\qquad\qquad\qquad\qquad 2H_2O(\ell) + 2e^- \rightarrow H_2(g) + 2OH^-(aq) \qquad E^0 = -0.83V$

At cathode reduction of $Cu^{2+}$ (aq) will be preferred over reduction of water as its standard reduction potential is more, than that of water.

Thus reaction at cathode : $Cu^{2+} + 2e^- \rightarrow Cu(s)$

**Anode (oxidation) :** $\qquad 2\,SO_4^{2-} \rightarrow S_2O_8^{2-} + 2e^- \qquad\qquad E^0 = -1.96$ V

$\qquad\qquad\qquad\qquad 2H_2O(\ell) \rightarrow O_2(g) + 4H^+ + 4e^- \qquad E^0 = -1.23$ V
At anode oxidation of water is preferred over oxidation of sulphate ion as its standard oxidation potential is more, than that of sulphate ion.

Thus reaction at anode : $2H_2O(\ell) \rightarrow O_2(g) + 4H^+ + 4e^-$

After electrolysis solution will become acidic (pH < 7)

**TG: @Chalnaayaaar** ALLEN®

**(e)** **Electrolysis of aq. $CuSO_4$ using Cu electrode.**

**Cathode (reduction) :** $Cu^{2+} + 2e^- \rightarrow Cu$ $E^0 = + 0.34$ V

$2H_2O(\ell) + 2e^- \rightarrow H_2(g) + 2OH^-$ $E^0 = -0.83$ V

At cathode reduction of $Cu^{2+}$ (aq) will be preferred over reduction of water as its standard reduction potential is more, than that of water.

Thus reaction at cathode :

$Cu^{2+} + 2e^- \rightarrow Cu(s)$

**Anode (oxidation) :** $SO_4^{2-} \rightarrow S_2O_8^{2-} + 2e^-$ $E^0 = -1.96$ V

$2H_2O(\ell) \rightarrow O_2(g) + 4H^+ + 4e^-$ $E^0 = -1.23$ V
$Cu(s) \rightarrow Cu^{2+} + 2e-$ $E^0 = -0.34$ V

At anode oxidation of copper solid is preferred over oxidation of water and sulphate ion, as its standard oxidation potential is more than that of water and sulphate ion.
Thus reaction at anode :

$Cu(s) \rightarrow Cu^{2+} + 2e-$

It is an example of electrolytic refining and there will be no change in the pH and concentration of electrolyte.
**(f)** **Electrolysis of dilute $H_2SO_4$ :**

**Cathode (reduction)** $2H^+ + 2e^- \rightarrow H_2(g)$ $E° = 0$

$2H_2O(l) + 2e^- \rightarrow H_2(g) + 2OH^-$ $E° = -0.83$ V

due to less availability of $H^+$ ions, it will not participate in formation of $H_2$ gas therefore reduction of water will take place.

**Anode (oxidation)** $SO_4^{-2} \rightarrow S_2O_8^{-2} + 2e^-$ $E° = -1.96$ V

$2H_2O(l) \rightarrow O_2(g) + 4H^+ + 4e^-$ $E° = -1.23$ V

oxidation of water is preferred over oxidation of sulphate ion as its standard oxidation potential is more, than that of sulphate ion.

**(g)** **Electrolysis of concentrated $H_2SO_4$**

**Cathode (reduction)** $2H^+ + 2e^- \rightarrow H_2(g)$ $E° = 0$

$2H_2O(l) + 2e^- \rightarrow H_2(g) + 2OH^-$ $E° = -0.83$ V
due to reduction of $H^+$ ions, formation of $H_2$ gas takes place.

**Anode (oxidation)** $SO_4^{-2} \rightarrow S_2O_8^{-2} + 2e^-$ $E° = -1.96$ V

$2H_2O(l) \rightarrow O_2(g) + 4H^+ + 4e^-$ $E° = -1.23$ V

due to oxidation of $SO_4^{2-}$ ions, formation of peroxydisulphate ion ($S_2O_8^{-2}$) takes place.

**(B)** **QUANTITATIVE ASPECTS OF ELECTROLYSIS**

1 mole $electron$ = $N_A$ electron = 96500 coulomb = 1 Faraday

$$\underset{1 mol}{Na^+} (aq) + \underset{1F}{e^-} \rightarrow \underset{1 mol}{Na}(s)$$

$$\underset{1 mol}{Cu^{+2}} (aq) + \underset{2F}{2e^-} \rightarrow \underset{1 mol}{Cu}(s)$$

Therefore, $$\underset{1 mol}{M^{+n}} (aq) + \underset{nF}{ne^-} \rightarrow \underset{1 mol}{M}(s)$$

nF charge discharges = 1 mol of $M^{+n}$ ion

$\therefore$ 1 F charge discharges = $\dfrac{1}{n}$ mol of $M^{+n}$ ion

= $\dfrac{1}{n} \times n = 1$ g equivalent of $M^{+n}$ ion

Hence $\boxed{1 \text{ mole } e^- = 1 \text{ F} = 1 \text{ g equivalent}}$

### FARADAY'S LAWS OF ELECTROLYSIS

**(a)** **First law of electrolysis :**

Amount of substance deposited or liberated at an electrode is directly proportional to amount of charge passed through the solution.

$W \propto Q$

W = amount of substance deposited, Q = charge in coulomb

W = ZQ

Z = electrochemical equivalent

when Q = 1 coulomb, then W = Z

Thus, amount of substance deposited or liberated by 1 coulomb charge is called **electrochemical equivalent.**

Let I ampere current is passed till 't' seconds .

Then, Q = I t $\qquad$ ∴ W = Z I t

1 Faraday = 96500 coulomb = Charge on one mole electrons

*One faraday is the charge required to liberate or deposit one gram equivalent of a substance at corresponding electrode.*

Let 'E' is equivalent weight then 'E' gram will be liberated by 96500 coulomb.

1 Coulomb will liberate $\dfrac{E}{96500}$ gram ;

By definition, $Z = \dfrac{E}{96500}$ $\quad$ ∴ $W = \dfrac{E I t}{96500}$ $\quad$ $\boxed{\dfrac{W}{E} = \dfrac{I t}{96500} = \text{number of g eq} = \text{number of faraday}}$

**(b)** **Second law of electrolysis :**

When same amount of charge is passed through different electrolyte solutions connected in series then weight of substances deposited or liberated at electrodes are in ratio of their respective equivalent weights. i.e. $\dfrac{W_1}{W_2} = \dfrac{E_1}{E_2}$

## GOLDEN KEY POINTS

### PRODUCTS OF ELECTROLYSIS OF SOME ELECTROLYTES

| S.No. | Electrolyte | Electrode | Product obtained at anode | Product obtained at cathode |
|-------|-------------|-----------|---------------------------|-----------------------------|
| (i) | Aqueous NaCl | Pt or Graphite | $Cl_2$ | $H_2$ |
| (ii) | Fused NaCl | Pt or Graphite | $Cl_2$ | Na |
| (iii) | Aqueous NaOH | Pt or Graphite | $O_2$ | $H_2$ |
| (iv) | Fused NaOH | Pt or Graphite | $O_2$ | Na |
| (v) | Aqueous $CuSO_4$ | Pt or Graphite | $O_2$ | Cu |

• For electrolysis $\Delta G = +ve$, So it is non-spontaneous process.
• In electrolytic cell D.C. current is used.

**TG: @Chalnaayaaar**

────────────── **Illustrations** ──────────────

**Illustration 16** How much electric charge is required to oxidise :

(a) 1 mol of $H_2O$ to $O_2$          (b) 1 mol of FeO to $Fe_2O_3$?

**Solution** (a) The oxidation reaction is :

$$H_2O \longrightarrow \frac{1}{2}O_2 + 2H^+ + 2e^-$$

1 mol          2 mol

$Q = 2F = 2 \times 96500 = 1.93 \times 10^5$ C

(b) The oxidation reaction is      $FeO + \frac{1}{2}H_2O \longrightarrow \frac{1}{2}Fe_2O_3 + H^+ + e^-$

$Q = F = 96500$ C

**Illustration 17** One mole each of electrons pass through solution of $AgNO_3$, $CuSO_4$ and molten $AlCl_3$ when Ag, Cu and Al are deposited at cathode. The molar ratio of Ag, Cu and Al deposited are

(1) 1 : 1 : 1       (2) 6 : 3 : 2       (3) 6 : 3 : 1       (4) 1 : 3 : 6

**Solution** Deposited equivalent will be same

1 eq.Ag = 1 mol Ag

1 eq.Cu = 1/2 mol Cu

1 eq.Al = 1/3 mol Al

$\Rightarrow$ ratio   $1 : \frac{1}{2} : \frac{1}{3} \Rightarrow 6 : 3 : 2$

**Illustration 18** Exactly 0.4 F electric charge is passed through three electrolytic cells connected in a series. First cell containing $AgNO_3$, second cell containing $CuSO_4$ and third cell containing $FeCl_3$ solution. How many grams of each metal will be deposited assuming only cathodic reaction in each cell.

**Solution** The cathodic reaction in the cell are respectively,

$$Ag^+ + e^- \longrightarrow Ag$$
1 mol    1 mol
108 g     1 F

$$Cu^{2+} + 2e^- \longrightarrow Cu$$
1 mol    1 mol
63.5 g    2 F
and      $Fe^{3+} + 3e^- \longrightarrow Fe$
1 mol    1 mol
56 g     3 F

Hence,      Ag deposited $= 108 \times 0.4 = 43.2$ g

Cu deposited $= \dfrac{63.5}{2} \times 0.4 = 12.7$ g

and      Fe deposited $= \dfrac{56}{3} \times 0.4 = 7.47$ g

**Illustration 19** An electric current of 100 A is passed through a molten liquid of sodium chloride for 5 hours. Calculate the volume of chlorine gas liberated at the electrode at NTP.

**Solution** The reaction taking place at anode is
$$2Cl^- \longrightarrow Cl_2 + 2e^-$$
71.0 g   71.0 g    $2 \times 96500$ C
        = 1 mol

$Q = i \times t = 100 \times 5 \times 60 \times 60$ C

The amount of chlorine liberted by passing $100 \times 5 \times 60 \times 60$ C of electric charge.

$$= \frac{1}{2 \times 96500} \times 100 \times 5 \times 60 \times 60 = 9.3264 \text{ mole}$$

Volume of $Cl_2$ liberated at NTP $= 9.3264 \times 22.4 = 208.91$ L

**Illustration 20** How long a current of 2 A has to be passed through a solution of $AgNO_3$ to coat a metal surface of 80 cm$^2$ with 5 μm thick layer? Density of silver = 10.8 g/cm$^3$.

**Solution**

$$d = \frac{M}{V} \Rightarrow 10.8 = \frac{M}{80 \times 5 \times 10^{-4}} \Rightarrow M = 10.8 \times 400 \times 10^{-4}$$

$$W = \frac{E \times I \times t}{96500} \Rightarrow 10.8 \times 400 \times 10^{-4} = \frac{108 \times 2 \times t}{96500} \Rightarrow t = 193 \text{ s}$$

## BEGINNER'S BOX-3

1. 1 L of 1 M $CuSO_4$ solution is electrolysed. After passing 2 F charge, the molarity of $CuSO_4$ will be

   (1) M/2       (2) M/4       (3) M       (4) zero

2. Same quantity of current is passed through molten NaCl and molten $Al_2O_3$. If 4.6 g of Na was deposited in one cell, the mass of Al deposited in other cell is :-
   (1) 0. 9 g       (2) 1.8 g       (3) 2.7 g       (4) 3.6 g

3. A certain current liberates 0.5 g of hydrogen in 2 hr. How many grams of copper can be deposited by the same current flowing for the same time in a copper sulphate solution?
   (1) 12.7 g       (2) 15.9 g       (3) 31.8 g       (4) 63.5 g

4. A quantity of electric charge that brings about the deposition of 4.5 g Al from $Al^{+3}$ at the cathode will also produce the following volume (STP) of $H_2(g)$ from $H^+$ at the cathode
   (1) 44.8 L       (2) 22.4 L       (3) 11.2 L       (4) 5.6 L

5. A current of 9.65 A is passed through the aqueous solution of NaCl using suitable electrodes for 1000 s. The amount of NaOH formed during electrolysis is
   (1) 2.0 g       (2) 4.0 g       (3) 6.0 g       (4) 8.0 g

6. If 0.224 L of $H_2$ gas is formed at the cathode, the volume of $O_2$ gas formed at the anode under identical conditions, is
   (1) 0.224 L       (2) 0.448 L       (3) 0.112 L       (4) 1.12 L
## 4.16 COMMERCIAL VOLTAIC CELLS

Batteries can be classified as primary and secondary. Primary batteries can not be returned to their original state by recharging, so when the reactants are consumed, the battery is "dead" and must be discarded. Secondary batteries are often called storage batteries or rechargeable batteries. The reactions in these batteries can be reversed; thus, the batteries can be recharged.

### (A) Primary cells : Dry cells and mercury cells

The most familiar type of battery is the dry cell which is acompact of Leclanche cell known after its discoverer Leclanche (fig.). In this cell, the anode consists of a zinc container and the cathode is a graphite rod surrounded by powdered $MnO_2$ and carbon. The space between the electrodes is filled with a moist paste of $NH_4Cl$ and $ZnCl_2$. The electrode reactions are complex, but they can be written approximately as follows.

Anode      $Zn(s) \longrightarrow Zn^{+2} + 2e^-$

Cathode      $MnO_2 + NH_4^+ + e^- \longrightarrow MnO(OH) + NH_3$
In the cathode reaction, manganese is reduced from the 4+ oxidation state to the 3+ state. Ammonia is not liberated as a gas but combines with $Zn^{2+}$ to form $Zn(NH_3)_4^{2+}$ ion. Dry cells do not have an indenfinite life as acidic $NH_4Cl$ corrodes the zinc container even when not in use. **Dry cells have a potential of approximately 1.25 to 1.5V.**

Carbon rod (cathode)

Zinc cup    $MnO_2$ + Carbon black + $NH_4Cl$

A commercial dry cell consists of a graphite (carbon) cathode in a zinc container; the latter acts as the anode

**Mercury cell,** suitable for low current devices like hearing aids, watches, etc. consists of zinc – mercury amalgam as anode and a paste of HgO and carbon as the cathode. The electrolyte is a paste of KOH and ZnO. The electrode reactions for the cell are given below :

Anode :   $Zn(Hg) + 2OH^- \longrightarrow ZnO(s) + H_2O + 2e^-$

Cathode : $HgO + H_2O + 2e^- \longrightarrow Hg(l) + 2OH^-$
The overall reaction is represented by

$$Zn(Hg) + HgO(s) \longrightarrow ZnO(s) + Hg(l)$$

The cell potential is **approximately 1.35 V** and remains constant during its life as the overall reaction does not involve any ion in solution whose concentration can change during its life time.

## (B)   SECONDARY OR RECHARGEABLE BATTERIES

The most important secondary cell is the lead storage battery. It consists of a **lead anode** and a grid of lead packed with **lead dioxide as cathode.** A solution of sulphuric acid (38 percent by mass or having density 1.30 gm cm$^{-3}$) is used as an electrolyte.

**Fig. The Lead storage battery**

When the cell discharges, it operates as a voltaic cell. The lead is oxidised to Pb$^{+2}$ ion and lead plates acquire a negative charge.
**At Anode :**           $Pb(s) \longrightarrow Pb^{+2} + 2e^-$                          .....(i)

Pb$^{+2}$ ions combine with sulphate ions of solution to form insoluble PbSO$_4$

$Pb^{+2} + SO_4^{\ 2-} \longrightarrow PbSO_4$ (Precipitation)          .....(ii)

_____

Overall reaction     $Pb(s) + SO_4^{2-} \longrightarrow PbSO_4(s) + 2e^-$
The electrons given by Pb are used at cathode (PbO$_2$ electrode)

**At Cathode :**
$PbO_2(s) + 4H^+ + 2e^- \longrightarrow Pb^{2+} + 2H_2O$          .....(iii)

$Pb^{+2} + SO_4^{-2} \longrightarrow PbSO_4$ (Precipitation)          .....(iv)

_____

$PbO_2(s) + 4H^+ + SO_4^{-2} + 2e^- \longrightarrow PbSO_4(s) + 2H_2O$

Therefore the overall cell reaction during discharging

$$Pb(s) + SO_4^{2-} \longrightarrow PbSO_4(s) + 2e^-$$

$$PbO_2(s) + 4H^+ + SO_4^{-2} + 2e^- \longrightarrow PbSO_4(s) + 2H_2O$$

_____

$$Pb(s) + PbO_2(s) + 2H_2SO_4 \longrightarrow 2PbSO_4(s) + 2H_2O$$
When a potential slightly greater than the potential of battery is applied, the battery can be recharged. During recharging the cell is operated like an **electrolytic cell** ie. now electrical energy is supplied to it from an external source. The electrode reactions are reverse of those that occur during discharge :
**At Cathode :** $\quad PbSO_4(s) + 2e^- \quad \longrightarrow Pb(s) + SO_4^{2-}$

**At Anode :** $\quad PbSO_4(s) + 2H_2O \longrightarrow PbO_2(s) + 4H^+ + SO_4^{-2} + 2e^-$

_____

$$2PbSO_4(s) + 2H_2O \longrightarrow Pb(s) + PbO_2(s) + 2H_2SO_4$$

It is clear that $H_2SO_4$ is used up during the discharge & produced during recharging reaction of cell.

**The discharging process of the storage cell is based on the principles of electrochemical cell, whereas the charging process is based upon the principles of electrolytic cells.**

**A** The battery consists of six two-volt cells connected in series.

**B** Each component cell is composed of several negative and positive electrodes made of pure spongy lead and lead oxide, respectively; the electrodes, connected in parallel, are immersed in a dilute solution of sulfuric acid.

**(C)** **Nickel - Cadmium ("Ni - Cd") batteries :**

They are used in variety of cordless appliances such as telephones, video camcorders, and cordless power tools, are lightweight and rechargeable. The chemistry of the cell utilizes the oxidation of cadmium and the reduction of nickel (III) oxide under basic conditions.

At cathode: $\quad [NiO(OH)(s) + H_2O(\ell) + e^- \rightarrow Ni(OH)_2(s) + OH^-(aq)] \times 2$

At anode: $\quad Cd(s) + 2\ OH^- \rightarrow Cd(OH)_2(s) + 2e^-$

_____

Net cell reaction : $\quad 2NiO(OH)(s) + Cd(s) + 2H_2O(\ell) \rightarrow 2Ni(OH)_2(s) + Cd(OH)_2(s)$

As the active masses of all reaction components are independent of their amount. The cell delivers constant EMF throughout.
**(D) Fuel Cells**

It is possible to make batteries in which the reactants are fed continuously to the electrodes. Electrical cells that are designated to convert the free energy from the combustion of fuels such as hydrogen, carbon monoxide or methane directly into electrical energy are called **fuel cells**.

One of the most successful fuel cells uses the reaction of hydrogen with oxygen to form water (fig.). This cell has been used for electric power in the Appollo space programme. The water vapours produced were condensed and added to the drinking water supply for the astronauts.

*Fig. : A simple fuel cell*
In the cell shown in figure hydrogen and oxygen are bubbled through a porous carbon electrode into concentrated aqueous sodium hydroxide. Catalysts are incorporated in the electrode. The electrode reactions are :

At anode : $2[H_2(g) + 2OH^-(aq) \longrightarrow 2H_2O(\ell) + 2e^-]$

At cathode : $O_2(g) + 2H_2O(\ell) + 4e^- \longrightarrow 4OH^-(aq)$

_____

Net cell reaction : $2H_2(g) + O_2(g) \longrightarrow 2H_2O(\ell)$

This cells runs continuously as long as the reactants are supplied. Since fuel cells convert the energy of a fuel directly to electricity, they are potentially more efficient than the conventional method of generating electricity on a large scale by burning hydrogen, carbon fuels or by using nuclear reactor. Although **theoretically we expect 100 percent efficiency in fuel cells, so far an efficiency of only 60-70 per cent has been attained**. Since fuel cells are efficient and free from pollution, efforts are being made to produce better commercially practical fuel cells.

**Efficiency of a Fuel Cell :** $\boxed{\eta = \dfrac{|\Delta G|}{|\Delta H|} \times 100}$

**Main features of different cells.**

| | Name of the cell/Battery | Anode | Cathode | Electrolyte |
|---|---|---|---|---|
| (i) | Dry cell | Zinc | Graphite surrounded by $MnO_2$ and C | $NH_4Cl + ZnCl_2$ (touching anode) |
| (ii) | Mercury cell | Zinc/Mercury Amalgum | Paste of HgO and carbon | Paste of KOH and ZnO |
| (iii) | Lead storage battery | Lead | Lead dioxide | $H_2SO_4$ (38%) |
| (iv) | Ni-Cd cell | Cadmium | Nickel dioxide | KOH sol. |
| (v) | $H_2$–$O_2$ fuel cell | Porous carbon containing catalysts ($H_2$ passed) | Porous carbon containing catalysts ($O_2$ passed) | Conc. aq. NaOH sol. |

## 4.17 CORROSION

Corrosion is basically an electrochemical phenomenon. The rusting of iron, the tarnishing of silver, development of a green coating on copper and bronze are some of the examples of corrosion. Corrosion causes enormous damage to building, bridges, ships and to many other articles made of iron.

In corrosion, a metal is oxidised by loss of electrons to oxygen and forms metal oxide. Corrosion of iron(which is commonly known as rusting) occurs in presence of water and oxygen (air). Although the chemistry of corrosion is complex but it is understood that at one spot of an iron object oxidation occurs and that spot behaves as an anode.

**Anode :** $Fe(s) \longrightarrow Fe^{2+}(aq) + 2e^-$ ; $(E^0_{Fe^{2+}/Fe} = -0.44V)$
Electrons released at anode move through the metal and go to another spot on the metal and reduce the oxygen in presence of $H^+$ ions (which is believed to be available from $H_2CO_3$ formed due to dissolution of $CO_2$ in water). This spot works as a cathode :

**Cathode :** $O_2(g) + 4H^+(aq) + 4e^- \longrightarrow 2H_2O(\ell)$ ; $(E^0 = 1.23 V)$
Here $Fe^{2+}$ ions move through water on the surface of the iron object. (If water present is saline, it will help more in carrying the current in the miniature cell thus formed and will enhance corrosion). The overall reaction of the miniature cell is the sum of the cathode and anode reactions as follows :

$$2Fe(s) + O_2(g) + 4H^+(aq) \longrightarrow 2Fe^{2+}(aq) + 2H_2O(\ell) ; E^0_{Cell} = 1.67 V$$
The $Fe^{2+}$ ions are further oxidised by atmospheric oxygen to $Fe^{3+}$ (as $Fe_2O_3$) and comes out as rust in the form of a hydrated iron (III) oxide expressed as $Fe_2O_3, xH_2O$.

$$4Fe^{2+}(aq) + O_2(g) + 4H_2O(\ell) \longrightarrow 2Fe_2O_3(s) + 8H^+$$
$H^+$ ions produced in the above reaction help further in rusting.

Impurities present in iron also enhance rusting by setting a number of miniature cells. Very pure iron does not rust quickly.

## 4.18 PREVENTION FROM CORROSION

Corrosion of a metal is prevented by applying protective coating (such as grease, paint, bisphenol or metal coatings) on metal surface. In case of iron this coating is done in two ways : (i) electrolysis (Cr, Ni and Cd coating) (ii) dipping iron objects in a molten metal (Zn and Sn coating). Use of zinc coating to protect iron is called Galvanisation. In galvanising iron, zinc being more reactive than iron serves as an anode and is oxidised

$(E^0_{Zn^{2+}/Zn} = -0.76V$ and $E^0_{Fe^{2+}/Fe} = -0.44V)$.

Here it is important to note that iron does not rust even after zinc coating is broken which is not true in case of tin coating over iron $(E^0_{Sn^{2+}/Sn} = -0.14V)$. Now if the coating is broken, iron is exposed and iron being more active than both copper and tin, is corroded. Here iron corrodes more rapidly than it does in the absence of tin. But tin protects copper in the same way as zinc protects iron $(E^0_{Cu^{2+}/Cu} = 0.34V)$.

Fig. : Galvanised iron. Cathodic protection of iron in contact with zinc is provided by galvanization.

Fig. : Cathodic protection by connecting a block of magnesium to an iron pipe burried underground.

Instead of coating more reactive metal on iron, the use of such metals is made as sacrificial anode. This method of preventing iron from corrosion is called CATHODIC PROTECTION.

In this method, a plate of reactive metal (Zn or Mg) is burried beside the iron pipe or tank and connected to it by wires.

Here iron becomes **cathode** and more reactive metal becomes **anode**. The reactive metal anode is sacrificed to protect the iron. Since these reactive metal plates are oxidised quickly, they are replaced from time to time which is easy to do.

Air
$O_2(g)$
Rust
$Fe_2O_3(s)$
$Fe^{2+}$
water
cathode    $e^-$    anode

$O_2 + 4H^+ + 4e^- \longrightarrow 2H_2O$   $Fe \longrightarrow Fe^{2+} + 2e^-$

*The rusting of iron (Iron in contact with water forms the anode and in contact with air forms the cathode. At the anode iron is oxidised to $Fe^{2+}$, and at the cathode oxygen is reduced to water*
